A Guide to Using the Geographical Infrastructure of Boston, MA

Overview

The Boston Area Research Initiative's Geographical Infrastructure for Boston (GI) is a database that organizes and links the geographical information for places and areas within Boston, MA at 17 different levels of geographic organization—including land parcels, streets, census geographies, and other administrative regions. The levels are organized in a hierarchy, with smaller geographic variables nested within larger (e.g., land parcels nested in census tracts). This is coordinated via variables that act as unique identifiers at each level. As a composite, the database is intended to facilitate aggregate calculations across levels of the hierarchy and analyses of data from different sources that reference the same geographical units. In particular, the database makes it possible to connect data sets generated by the City of Boston with census geographies and data.

In addition, in 2018 we have introduced the Networked Geographical Infrastructure (NetGI), which describes the physical linkages between the objects contained in a single level of the GI. These support analysis of connectivity across the streets and neighborhoods of Boston.

The levels are each documented in a .csv and in most cases a .shp (shapefile for GIS), and include:

- Properties (from the City of Boston Property Assessment Database, 2017)
- Land parcels (aggregated from the City of Boston Property Assessment Database, 2018)
- Intersections (from the City of Boston and from TIGER line data, 2013)
- Street segments (from census TIGER line data, 2013)
- Census blocks, block groups, and tracts (from census 2010)
- Ten ways that the City of Boston divides the city into administrative districts for planning, elections, and operations.
- An ID connector for linking to the Master Address List, a database of addresses used by the City of Boston that we don't include in this infrastructure.

The NetGI consists of matrices and edge lists, stored in .csvs:

Travel adjacency matrices (including Seven different travel measures between census block groups and between census tracts (based on population weighed centroids)

- Street intersection edge list (list of streets in Boston that intersect with each other. Using the shape files from BARI's 2013 roads)

This documentation contains a section for each of these groupings, describing the contents and variables. For each, the unique identifier variables used to link the files are noted.

1. Properties

1.1. Description of Contents

The City of Boston's Assessing Department is responsible for determining accurate values for all properties in the city. To this end the Department maintains parcel ownership and value information to ensure fair assessment of both taxable and non-taxable property in Boston. Assessing records are compiled and reviewed annually to reflect changes to parcels as a result of new construction, remodeling, and changes in ownership. This forms the City of Boston Property Assessment Database, which acts as the fundamental dataset for BARI's geographical infrastructure.

The data contained herein are a modified version of the original Property Assessment Data Set, and describe the parcel-specific address, ownership, and land use for the 168,181 properties in Boston. They include variables and measures from the original data, some of which are cleaned or modified by BARI, as well as derived measures based on original variables.¹

No shapefile is included for Properties because the polygons associated with the City of Boston's Property Assessment Database are Land Parcels. Each property exists on only one land parcel from the Land Parcels database, but there may be multiple properties on a Land Parcel. The information necessary to split the Land Parcels appropriately into properties is not available, and properties may exist on top of one another on different floors anyway. Note that the definition of Land Parcel in this database is slightly different from that of the City of Boston's original data files in that we combine a small number of land parcels that are differentiated by the City (see Section 2 for more detail).

Unique identifier: *parcel_num*

1.2. Description of Variables

Property variables are split into three categories: identifying characteristics, property and building characteristics, and geographical information. Identifying characteristics include variables regarding the basic identity and attributes of the address. Building characteristics include information on the physical attributes of the building containing the property. Geographical information provides further detail on the location of the property and the other geographies that contain it.

The Tax Assessor's department maintains a large number of property and building characteristic variables, but here we only include those relevant to its geographic utility. For access to the full breadth

¹ Tax rate calculation information published by the City of Boston Assessing Department through the department's website: <http://www.cityofboston.gov/assessing/taxrates.asp>

of variables and their documentation see BARI's Property Assessment Database².

1.2.1. Identifying Characteristics

- *parcel_num* is the 10-digit property identification number, unique to each property. The first two digits indicate the Ward, digits 3 thru 7 are the parcel, and digits 8 thru 10 are the sub-parcel.
- *CM_ID* is the 10-digit property number of the main condo building property. All condo units in each building are related to this number.
- *GIS_ID* is another 10-digit property identification number. It is the unique identifier for the plot the property is in.
 - *Note:* This differs slightly from *Land_Parcel_ID*, which combines multiple *GIS_ID* values based on certain criteria (see Section 2).
- *ST_NUM* is the street number of the property.
- *ST_NAME* is the street name of the property.
- *ST_NAME_SUF* is the suffix of the street name. This variable contains two-character short-forms of each type of suffix (St, Av, BL, PL, etc...)
- *ZIPCODE* is the zip code of the property.
- *Unit_N* is one estimation of the number of units within the property
 - *Note:* Tabulated from the City of Boston's Street and Address Management (SAM) system. For cases without unit data in SAM values are imputed (see Appendix D for methodology).
- *Unit_N_Original* is a more conservative but less complete estimate of the number of units within the property.
 - *Note:* Only for cases with unit data in SAM.

1.2.2. Property and Building Characteristics

- *LU* is the Land Use type for the property. Codes for land use can be found in Appendix A.

² <https://dataverse.harvard.edu/dataset.xhtml?persistentId=doi:10.7910/DVN/UWTQ4E>

- *OWN_OCC* is a one-character code that indicates if an owner receives a residential exemption for the property. A "Y" indicates that the owner claims to live within the property (a.k.a. the property is "owner-occupied") and a "N" indicates the opposite.
- *YR_BUILT* is the year in which the property was built. The original dataset held many properties whose year of construction was listed as zero. It was fixed by updating the *YR_BUILT* variable, which now contains a "NA" value where it previously showed a "0".
- *YR_REMOD* is the year in which the property was last remodeled. For some properties the year of its most recent remodel was listed as zero. It was fixed by updating the *YR_REMOD* variable, which now contains a "NA" value where it previously showed a "0".
- *LAND_SF* is the total size of the property in square feet. This is also known as the lot size.
- *GROSS_AREA* is the gross floor area for commercial properties.
- *NUM_FLOORS* is the number of levels in the structure that is located on the property.

1.2.3. Geographical Information

Geographical information for the properties comes from multiple sources in order to coordinate them with census geographies. First, latitude and longitude of the property was derived as the centroid of the containing land parcel, based on the .shp provided by the City of Boston (see Section 2). Properties were then linked to the appropriate census TIGER line road segment, defined as the nearest road segment to the x-y coordinate that matched on street name. This was done instead of geocoding because City of Boston land parcels will be more accurate about the location of numbers along the segments of a street than census TIGER line data. Last, all properties were linked to the containing census block and higher geographies by spatial overlay.

- *X* is the geo-coded longitude of the property.
- *Y* is the geo-coded latitude of the property.
- *Land_Parcel_ID* is the unique identifier for the land parcel the property is in.
- *TLID* is the identifier for the census TIGER line road segment containing the property.
- *Blk_ID_10* is the 2010 census Block ID number
- *BG_ID_10* is the 2010 census Group ID number
- *CT_ID_10* is the 2010 census Tract ID number

- *NSA_NAME* is the name of the Inspectional Service Department Neighborhood Statistical Area in which the building is located.
- *BRA_PD* is the name of the Boston Redevelopment Authority Planning District in which the building is located.

2. Land Parcels

2.1. Description of Contents

This dataset contains the unique land parcels present in the City of Boston's Property Assessment Database (see Section 1). It was constructed by merging all properties that match on *GIS_ID* or on street address. Note that the first step may combine certain *GIS_ID*s into a single Land Parcel. This is important because the City of Boston considers every *GIS_ID* as its own "land parcel," but for the purposes of this database we have combined a small number that have the same address because they would otherwise be impossible to differentiate. Then, matches were split if the properties within them were more than 16 meters apart from one another, making them too far away from each other to make sense as a single land parcel, but only if they had different *GIS_ID* values. This processing reduced the number of land parcels from 99,191 in the City's original database to a final set of 97,852 unique land parcels. In addition to a CSV, we include a shapefile, which is the shapefile maintained by the City of Boston for its Property Assessment Database.

Unique Identifier: Land_Parcel_ID

2.2. Description of Variables

Land parcel variables are split into three categories: identifying characteristics, property characteristics, and geographical information. Identifying characteristics include variables regarding the basic identity and attributes of the address. Building characteristics include information on the physical attributes of the buildings contained by the land parcel. Geographical information provides further detail on the location of the parcel and the other geographies that contain it.

2.2.1. Identifying Characteristics

- *Land_Parcel_ID* is the unique identifier for land parcels.
- *Full_address* is split into four parts: lower number, upper number, street, and zip code. It contains an upper and lower number to allow for a range of addresses along a street.
- *property_N* is the total number of the properties in each land parcel.
- *Unit_N* is the number of units within the property, summed from the properties therein (see Section 1.2.1).
- *Unit_N_Original* is the raw number of units within the property, summed from the properties therein (see Section 1.2.1).

2.2.2. Property and Building Characteristics

- *AV_LAND* is the assessed value of the land.
- *AV_BLDG* is the total assessed value for the building on the properties on the parcel.
- *AV_TOTAL* is the total assessed value for the properties on the parcel. It is a summation of the assessed values of the land and building.
- *LAND_SF* is the total size of the properties in square feet on the parcel. This is also known as the lot size.
- *GROSS_AREA* is the gross floor area for commercial properties on the parcel.
- *LIVING_AREA* is the total living area for residential properties. on the parcel.
- *LU* is the designated land use of the address.
- *OWN_OCC* is the proportion of properties in the land parcel that are occupied by their owner.
- *NUM_FLOORS* is the number of levels in the structure that is located on the property.
- *YR_BUILT* is the year in which the property was built. The original dataset held many properties whose year of construction was listed as zero. It was fixed by updating the *YR_BUILT* variable, which now contains a "NA" value where it previously showed a "0".
- *YR_REMOD* is the year in which the property was last remodeled. For some properties the year of its most recent remodel was listed as zero. It was fixed by updating the *YR_REMOD* variable, which now contains a "NA" value where it previously showed a "0".
- *R_BLDG_STYL* is the building style for residential properties. The styles are: BL for Bi-Level, BW for Bungalow, CL for Colonial, CN for Contemporary, CP for Cape, CV for Conventional, DK for Decker, DX for Duplex, L for Tri-Level, Oth for Other, RE for Row End, RM for Row Middle, RN for Ranch, RR for Raised Ranch, SL for Split Level, TF for Two-Family Stack, TD for Tudor, SD for Semidetached, and VT for Victorian It is calculated by taking the mode of the building styles of the properties in the land parcel.
- *owner_address* is the street address of the owner of the land parcel. It is calculated by taking the mode of the owner's street address for all properties in the land parcel.
- *center* indicates whether a land parcel contains a community center (1) or not (0).

- *Note:* Sourced from the City of Boston’s Department of Innovation and Technology’s “Community Centers” dataset on Analyze Boston (updated May 9, 2018).
- *medhos* is a dummy variable indicating whether the land parcel contains a hospital, medical facility, medical office, nursing facility, rehabilitation facility, and/or a convalescent facility (1) or not (0). It was formulated from the City of Boston’s 2018 Property Assessment database using the land use Property Type (PTYPE) designations of 304, 305, 309, 342, 953, 954, 958, 959, and 979. This information was cross checked with the City of Boston’s Department of Innovation and Technology’s “Hospital Locations” dataset on Analyze Boston. It was last modified October 19, 2017.
- *supermkt* is a dummy variable indicating whether the land parcel contains a supermarket (1) or not (0). It was formulated from the City of Boston’s 2018 Property Assessment database using the land use Property Type (PTYPE) designation of 324.
- *parking* is a dummy variable indicating whether the land parcel contains a public or private parking lot or garage (1) or not (0). It was formulated from the City of Boston’s 2018 Property Assessment database using the land use Property Type (PTYPE) designations of 116, 336, 337, 338, 339, 387, 961, and 962.
- *vacant* is a dummy variable indicating whether the land parcel contains a publicly-owned or privately-owned vacant property (1) or not (0). It was formulated from the City of Boston’s 2018 Property Assessment database using the land use Property Type (PTYPE) designations of 012, 130, 131, 132, 202, 211, 390, 391, 392, 393, 440, 441, 442, 986, and 987.
- *rel* is a dummy variable indicating whether the land parcel contains a property owned by a religious institution/organization and/or housing for a religious institution/organization (1) or not (0). It was formulated from the City of Boston’s 2018 Property Assessment database using the land use Property Type (PTYPE) designations of 129, 906, 970, 971, and 379.

2.2.3. Geographical information

- *X* is the X coordinate of the land parcel, in longitude.

- It is calculated by taking the modal X, Y pair among aggregated properties.
- *Y* is the Y coordinate of the land parcel, in latitude.
 - It is calculated by taking the modal X, Y pair among aggregated properties.
- *TLID* is the identifier for the segment of road containing the properties on the parcel.
 - This is found by subsetting the 2013 TIGER lines street segments to only those that match the street name of the property, and then finding the one that is geographically closest to the property.
- *Blk_ID_10* is the 2010 Census Block ID number.
 - This is found by spatially overlaying the longitude and latitude of the property onto the Census Blocks shapefile.
- *BG_ID_10* is the 2010 Census Group ID number.
- *CT_ID_10* is the 2010 Census Tract ID number.

3. Intersections

3.1. Description of Contents

Intersections comprise two datasets. One is a catalog of all intersections (*Intersections*; 11,116) generated by the census TIGER line roads data from 2013. The other is a master list of intersections maintained by the City of Boston (*Intersections (City)*; 8,421) that has then been merged with intersections within the census TIGER line road map (to the same intersection name when possible, otherwise to the closest point).

Unique identifiers: *ObjectID* (census intersections), *propid* (City intersections).

3.2. Description of Variables

Variables are largely equivalent between the two files. The two datasets can be connected via their unique identifiers. They are split into two categories: identifying characteristics and geographical information. Identifying characteristics includes variables regarding the basic identity and attributes of the intersection. Geographical information provides further detail on the location of the intersection and the other geographies that contain it.

3.2.1. Identifying Characteristics

- *ObjectID* is the unique identifier for census-generated intersections.
- *Propid* is the unique identifier for City-defined intersections.
- *Address*, indicating the two roads that form the intersection.
- *TLID* is the unique identifier for the road segment to which the intersection is attributed.
 - *Note:* Intersections are attributed to the road that forms the intersection that is most predominant in terms of main/non-main street and zoning.
- *X* gives the x-coordinate of the intersection
- *Y* gives the y-coordinate of the intersection
- *Main* indicates whether the primary road segment is a main street or not.
- *RoadType* gives the zoning status of the road. See *Zoning* in *Roads* (Section 4).
 - *Note:* Possible values for this are Commercial, Residential, Exempted, Independent, or None.

3.2.2. Geographical Information

- *BG_ID_10* is the unique identifier for the census block group in which the intersection is located.
- *CT_ID_10* is the unique identifier for the census tract in which the intersection is located.

4. Roads

4.1. Description of Contents

This dataset contains a complete list of all road segments in Boston, MA, as defined by census TIGER Line data as of the 2013 update. It contains 24,891 segments.

Unique Identifier: *TLID*

4.2. Description of Variables

Roads variables are split into two categories: identifying characteristics and geographical information. Identifying characteristics includes variables regarding the basic identity and attributes of the address. Geographical information provides further detail on the location of the road and the other geographies that contain it. Because roads often form the borders between regions, nesting in higher levels was done using the road centroids.

4.2.1. Identifying Characteristics

- *TLID* is the unique identifier for the road segment.
- *STATEFP* is the unique identifier (FIPS code) for the state containing the road segment (25 = Massachusetts).
- *COUNTYFP* is the unique identifier (FIPS code) for the county containing the road segment (025 = Suffolk).
- *TFIDR* is the unique identifier for the right side of the road segment.
- *TFIDL* is the unique identifier for the left side of the road segment.
- *MFTCC* is a code provided by the census for the type of road. These types are listed in Appendix B.
- *FULLNAME* is the name of the road.
- *LFROMADD*, *LTOADD*, *RFROMADD*, and *RTOADD* give the address ranges for the left and right sides of the road.
- *ZIPL* and *ZIPR* is the zipcode containing the left and right sides of the road respectively.

- *Length* is the length of the segment in meters.
- *CLASS* describes the nature of the road, as provided by Massachusetts Dept. of Transportation.
 - *Note:* Values taken: 1 – Limited access highway; 2 – Multi-lane highway, not limited access; 3 – Other numbered route; 4 – Major road – arterials and collectors; 5 – Minor street or road with road inventory information; 6 – Minor street or road with no road inventory information.
- *RDTYPE* is an extended version of the *CLASS* variable, provided by Massachusetts Dept. of Transportation.
 - *Note:* 1-6 remain the same. 7 – Ramp; 8 – Tunnel; 9 – Tunnel for limited access highway; 10 – Tunnel for a multi-lane highway, not limited access; 11 – Tunnel for other numbered route.
- *Cluster* indicates the cluster number to which the segment was attributed, from a cluster analysis based on the zoning characteristics of the parcels on the street. More details on the clusters are available in Appendix C.
 - *Note:* Clusters were redetermined before the 2018 release based on the greater specificity of parcels and land uses. This variable is not equivalent to the same variable in previous releases.
 - *Note:* 1 = *Three-Family Residential with Assorted Other Uses* (24% of streets with parcels); 2 = *Mix of Two-Family and Single-Family Residential* (17%); 3 = *Commercial* (10%); 4 = *Single-Family Residential Only* (25%); 5 = *Exempt* (10%); 6 = *Condominiums* (10%); 7 = *Mixed-Use Commercial* (4%). See Appendix C for more detail on the average street in each.
- *Main* indicates if a road segment is considered part of a main street (“1” = Main)
 - *Note:* Based on MassGIS’ *Class*, with all classes less than 5 denoted as main streets.

4.2.2. Geographical Information

The following variables indicate which census regions (block groups and tracts) the street segment falls in. These were calculated in two ways. First, streets with at least one parcel took the modal value for census block group of the parcels sitting on it. Tract was then determined as the one containing that census block group. Streets with no parcels on them were attributed to the census geography that contained its centroid. This process ensured that a street was not attributed to a region that contained few or none of its parcels, as those are the locations that would presumably drive most of the activity on the street that would be of interest for analysis. Importantly, this means that in a minority of cases (___) the census tract containing the modal census block group was *not* the same as the modal census tract (e.g., a street at the intersection of three census block groups in two tracts, with three parcels in the one census block group in one census tract, and two parcels in each of two census block groups in the other census tract). We decided to keep these cases as they are in order to maintain strict nesting between block groups and tracts.

Note: This methodology was new in the 2018 release. Previous releases used the centroid to link all streets to census geographies. It altered approximately 9% of attributions from previous releases and about 18% for streets with parcels for block groups; the same proportions were 5% and 10% for tracts.

- *BG_ID_10* is the unique identifier for the census block group (2010-present) in which the segment is located (see Section 5).
- *CT_ID_10* is the unique identifier for the census tract (2010-present) in which the segment (see Section 5).

5. Census Geographies

5.1. Description of Contents

As of the 2010 census, Boston, MA contains 7,288 city blocks, defined as any piece of land bounded by streets or water on all sides, and not divided by any streets or water. These are nested in 558 block groups, which are themselves nested in 178 census tracts. Census geographies are a natural hierarchy, with the unique identifier at each level being an extension of the level above it, indicating the specific region and all of the higher-order regions that contain it.

5.2. Description of Variables

Census variables are split into two categories: identifying characteristics and geographical information. Variables are consistent across all three census levels, though some variables appear in one file and not in others. Identifying characteristics includes variables regarding the basic identity and attributes of the block. Geographical information provides further detail on the location of the block and the other geographies that contain it. Nesting started with the block level, because all geographies, census or otherwise, conform to block boundaries. Linking to non-census geographies was done by identifying the location of the centroid of each block.

Because block groups and tracts do not nest perfectly within non-census geographies, this linking was done by identifying the region that contained the plurality of the block group or tract's land area. Some non-census geographies crossed over census the boundaries of a particular level too often, however, to make such linkages reliable, and thus were omitted: for block groups, *Precincts* were not linked; for tracts, *Precincts*, *Neighborhood Statistical Areas*, and *ZIP Codes* were not linked.

Demographic and socioeconomic data for census geographies can be found online in our Dataverse, at https://dataverse.harvard.edu/dataverse/Massachusetts_Census_Indicators.

Unique Identifiers: Block: *Blk_ID_10*; Block groups: *BG_ID_10*; Tracts: *CT_ID_10*

5.2.1. Identifying Characteristics

- *STATEFP* is the unique identifier (FIPS code) for the state containing the region (25 = Massachusetts).
- *COUNTYFP* is the unique identifier (FIPS code) for the county containing the region (025 = Suffolk).
- *TRACTCE10* is the code identifying the census tract.

- *BLOCKCE10* is the code identifying the block
- *GEOID10* is the unique identifier (FIPS code) of the region.
- *NAME10* the block name, within the tract.
- *MTFCC10* a class code indicating the type of feature.
- *ALAND10* is the land area of the region (in sq. meters).
- *AWATER10* is the water area of the region (in sq. meters).
- *INTPTLAT10* is the latitudinal coordinate of the region.
- *INTPTLON10* is the longitudinal coordinate of the region.
- *POP100_RE* is the population of the region as of 2010.
- *HU100_RE* is the number of housing units in the region as of 2010.
- *Type* describes the type of neighborhood the region is within.
- *Note:* Possible values are Residential, Downtown, Institutional (e.g., industrial, college campuses), and Park. Only for block groups and tracts.
- *Res* indicates whether the block group is generally a residential area (based on *Type*; “1” = yes).

5.2.2. Geographical Information

- *Blk_ID_10* is the unique identifier for the block (identical to *GEOID10* in the block file, but compatible with the other levels).
- *BG_ID_10* is the unique identifier of the census block group (identical to *GEOID10* in the block file, but compatible with the other levels).
- *CT_ID_10* is the unique identifier of the census tract (identical to *GEOID10* in the block file, but compatible with the other levels).
- *BOSNA_R_ID* is the numerical unique identifier for the Boston Redevelopment Authority Neighborhood Statistical Area in which the region is located (see Section 7).
- *NSA_NAME* is the name of the Boston Redevelopment Authority Neighborhood Statistical

Area in which the region is located (see Section 7).

- *BRA_PD_ID* is the unique identifier for the Boston Redevelopment Authority planning district in which the region is located (see Section 7).
- *BRA_PD* is the name for the Boston Redevelopment Authority planning district in which the region is located (see Section 7).
- *ZIPCODE* refers to the ZIP code in which the region is located (see Section 7).
- *City_Counc* is the unique identifier for the city council district in which the region is located (see Section 7).
- *WARD* is the unique identifier for the election ward in which the region is located (see Section 7).
- *PRECINCTS* is the unique identifier for the election precinct in which the region is located (see Section 7).
- *ISD_NAME* is the name for Boston Inspectional Services Department neighborhood in which the region is located (see Section 7).
- *Police_Dis* is the unique identifier for the police district in which the region is located (see Section 7).
- *Fire_Distr* is the unique identifier for the fire district in which the region is located (see Section 7).
- *PWD* contains a numerical unique identifier for Public Works districts, followed by the name of the Public Works District in which the region is located (see Section 7).

5.2.3. Population weighted centroids

5.2.3.1. Description of contents

To find more accurate estimates of where individuals live within Boston's block groups and census tracts, population weighted centroids were calculated using the population of the census blocks therein. Populations were obtained using the *demographics* command of the

UScensus2010blk package³. Shape files for all relevant blocks were obtained using the *blocks* command of the *tigris* R package⁴. First, centroids were found for each block. Then, population weighted centroids were calculated for each census block group and tract based on the location of each block's centroid and its proportion of the total population. If a block group had zero population, then an unweighted average of the blocks' centroids was calculated. FIPS code is maintained as the unique identifier for each census block group and tract. Block groups are embedded within tracts, and the data reflect this nesting. The related file is "pop.centroids.csv".

5.2.3.2. Description of variables

The variables are split into the areal units' unique FIPS codes and the coordinates of their population weighted centroids. All 558 block groups appear only once, but the 178 census tracts appear multiple times based on the number of block groups.

5.2.3.3. Identification Variables

- *BG_ID_10* is the 2010 census block group ID number.
- *BG_ID.char* is the character version of block groups' ID number with "bg" added to the front.
- *CT_ID_10* is the 2010 census tract ID number.
- *CT_ID.char* is the character version of census tracts' ID number if "ct" added to the front.

5.2.3.4. Centroid Variables

- *cen.bg_lat* is the latitude of block groups' centroids.
- *cen.bg_long* is the longitude of block groups' centroids.
- *cen.ct_lat* is the latitude of tracts' centroids.
- *cen.ct_long* is the longitude of tracts' centroids.

6. Other Geographies

6.1. Description of Contents

Other geographies were provided by the City of Boston. They include: traditional neighborhoods defined by the Boston Redevelopment Authority (*BRA Neighborhood Statistical Areas, BRA Planning Districts*); election board regions (*City Council Districts, Election Precincts, Election Wards*); and districts for City operations (*Fire Districts, ISD Neighborhoods, Police Districts, Public Works Districts, and ZIP Codes*). For each, only a shape file with the unique identifiers is included. The unique identifiers are listed below.

6.2. Description of Variables

6.2.1. BRA Neighborhood Statistical Areas

- *BOSNA_R_ID* is the numerical unique identifier.
- *ID* an additional identifier used by the BRA.
- *NSA_NAME* the name of the neighborhood statistical area.

6.2.2. BRA Planning Districts

- *ID* is the numerical unique identifier. Denoted as *BRA_PD_ID* in lower-level files.
- *PD* is the name of the planning district. Denoted as *BRA_PD* in lower-level files.

6.2.3. City Council Districts

- *DISTRICT* is the unique identifier. Denoted as *CITY_COUNC* or *CITY_COUNCIL* in lower-level files.
- *Councillor* is the individual holding the seat as of the 2013 election.

6.2.4. Election Precincts

- *PRCNTS_ID* is the unique identifier. Denoted as *PRECINCT* in lower-level files.
- *WDPCT* is a concatenation of the ward number and the precinct number within the ward.
- *PCT* is a count within the precinct, making it non-unique.

6.2.5. Election Wards

- *WARD* is the unique identifier.
- *CNT_WARD* is the number of precincts in each ward.

6.2.6. Fire Districts

- *DISTRICT* is the unique identifier. Denoted as *Fire_Distr* in lower-level files.

6.2.7. ISD Neighborhoods

- *Name* is the unique identifier.

6.2.8. Police Districts

- *ID*
- *DISTRICT_* is the unique identifier for the police district of the block. Denoted as *Police_Dis* in lower-level files.

6.2.9. PWD Districts

- PWD
- NAME
- COMBO contains a numerical unique identifier for Public Works districts, followed by the name of the Public Works District. Denoted in lower-level files as PWD.

6.2.10. ZIP Codes

- *ZIP5* is the zip code. Denoted as *ZIPCODE* or *ZIP* in lower-level files.

7. ID Connector

7.1. Description of Contents

Previous to the 2016 Geographical Infrastructure, BARI used the City of Boston's Master Address List (or Street and Address Master, SAM) as the fundamental file for the geographical infrastructure. The Master Address List is described as containing "all property addresses in the city." Starting in the 2016 geographical infrastructure, we decided to use the Property Assessment Database as the fundamental file instead. We chose not to use the Master Address List because we found a number of redundancies and inconsistencies in the data, which created an inaccurate picture of the physical infrastructure of Boston. It appeared that the dataset had been added to in certain places without purging old data, resulting in the same property represented in multiple ways and inconsistency between properties. By contrast, the Tax Assessor's Database covered the same information in a highly regular and consistent way. Starting in 2017, the City of Boston has made the Master Address List a legacy dataset and appears to be phasing it out of use.

The difficulty with removing the master address list from our geographical infrastructure is that many data systems in Boston, such as building permits, make use of the Master Address List's unique ID, *Property_ID* or *SAM_ID*, to connect their data to an address. Even if the City of Boston switches to using the Property Assessment database completely, old datasets will make use of the Master Address List's unique ID. To facilitate use of any geographies that have only *Property_ID*, we have included an ID Connector, a .csv file with *Property_ID*, *parcel_num* (the unique ID for properties), *Gis_ID*, and *Land_Parcel_ID* (the unique ID for land parcels) for all instances of all four IDs. There are 352,049 rows and the four IDs are nested within one another, following an m:1, m:1, m:1 relationship, although in some cases there are *parcel_num* IDs without a corresponding *Property_ID*, and in some cases a *Property*.

8. Travel adjacency matrices

8.1. Description of contents

Seven different travel measures between census block groups and between census tracts (based on population weighted centroids, see Section 5.2.3; two separate sets of files) were found. Below is a description of each file with additional information for how the measures were collected. In all of the files, the character versions of block group and census FIPS codes from the centroid files are the row and column names; this way the files can be used together easily. See additional considerations (section 9.3 below) for information on when values needed to be re-queried. Note that we are using the term “adjacency matrix” in the network sense, which is distinct from the use of adjacency (i.e.; contiguity) matrix in spatial analyses. If one wishes to use these matrices for spatial analyses, then one can use the R package *spdep* to create the contiguity matrix⁵

The first measure found is the geometric distance (or “as the crow flies”) between areal units. Three different travel measures for driving were found using the Google Maps Distance_Matrix API. The API provides travel distances and times between areal units’ centroids using the optimized route. The query was set to use the “best guess” model (rather than pessimistic or optimistic). The matrices are asymmetric indicating that the relationships are not always equal. The rows indicate the origin and the columns indicate the destination. Three different measures of public transit were found using the Google Maps Directions API between areal units’ centroids. The Directions API was used because the complete directions were needed to calculate the number of boardings of public transit from origin to destination. In these queries, mode was set to ‘transit’ and departure time was still Noon on August 1st. All of the matrices are asymmetric.

8.2. Description of files

Each of the seven types of travel relations exists for both census block groups and tracts. Below, we describe the contents of each file in terms of census block groups (with the prefix “bgs_”), and the same relations with the prefix “cts_” identifies the files for census tracts.

- *bgs_crow.flies.csv* contains the geometric distance between block groups (in meters), or “as the crow flies”. This was done with the *distGeo* command from the *geosphere* R package⁶.

⁵ Bivand, R., Altman, M., Anselin, L., Assunção, R., Berke, O., Bernat, A., & Blanchet, G. (2015). Package ‘spdep’. See <ftp://garr.tucows.com/mirrors/CRAN/web/packages/spdep/spdep.pdf>.

⁶ Hijmans, R. J., Williams, E., & Vennes, C. (2017). *geosphere: Spherical Trigonometry*. R package version 1.5-7. Available at <https://CRAN.R-project.org/package=geosphere>.

The matrices are symmetric and the diagonal is 0.

- *bgs_drive.dist.csv* contains the driving distance in meters between census block groups.
- *bgs_drive.dur_avg.csv* contains the average driving duration in seconds between census block groups.
- *bgs_drive.dur_wed.csv* contains the driving duration in seconds between census block groups queried for Wednesday at noon two weeks from query data. This was done so that local daily traffic patterns would not impact the route or duration.
- *bgs_transit.distance.csv* contains the transit distance in meters between two census block groups.
- *bgs_transit.duration.csv* contains the transit duration in seconds between two census block groups.
- *bgs_transit.transfers.csv* contains the number of distinct boardings (train or bus) that an individual would take between two census block groups. A value of 0 indicates that walking is fastest, and thus, no boarding is needed.

8.3. Additional considerations

One block group represented Long Island, located in Boston Harbor and managed as part of the Boston Harbor Islands National Recreation Area. Travel via driving and transit to and from this block group was listed as “Unnavigable” in the datasets. Occasionally, Google Maps API returns outputs that state that two locations do not have transit directions between them, or that the API doesn't support all mode='transit' between these two locations, even though the Google Maps website does. This occurred for two pairs of census tracts and over forty pairs of block groups. These points were originally listed as “NO_RESULTS” but were later re-queried. All but twelve pairs provided results when re-queried with the exact latitude and longitude coordinates a week later. For these twelve, the latitude and longitudes of origin and destination were both increased such that they represented points 80 meters to the North and 80 meters to the East of the actual centroid. This small change was enough to get to points where Google Maps would provide the transit directions. The remaining four were augmented in coordinate points by 400 meters instead of 80 meters.

9. Street intersection edgelist

9.1. Description of contents

The file contains the edge list of streets in Boston that intersect with each other. Using the shape files from BARI's 2013 roads, we used the *st_intersect* command from the *sf* package in R to find which streets intersect⁷. From the 24,891 street segments, there are 47,493 intersection pairs between streets. Each pair represents a dyad in a network, where streets are nodes. The edge list contains all of these dyads. The relationship is undirected. The file "streets.intersections.el.csv" contains the unique tiger line IDs for each street. The names have "tl" added to the numeric ID, so that they can be used as the node IDs in the network. Note that the way intersections were found includes any intersections between the streets' shape files; thus, this does not account for over/under passes.

⁷ Pebesma, E. (2017). *sf*: Simple features for R. R package version 0.5-0. Available at <https://cran.r-project.org/web/packages/sf/index.html>.

APPENDIX A. Codes for Land Use

USE CODE	DESCRIPTION
R1	Residential 1 Family
R2	Residential 2 Family
R3	Residential 3 Family
R4	Residential 4 - 6 Units
A	Residential 7 or more Units
RL	Residential Lot
CD	Condominium
CC	Commercial Condominium
CM	Condo Main (Bldg. broken into condo units)
C	Commercial
RC	Mixed Residential Commercial
CL	Commercial Land
CP	Condo Parking
I	Industrial
E	Exempt
EA	Exempt (Chapter 121A)

APPENDIX B. Codes for Road Types

MTFC C	Feature Class Full Name	Count
H110 0	Connector (Hydrography)	198
H301 0	Stream/River	12,855
H302 0	Canal, Ditch or Aqueduct	520
L401 0	Pipeline	7
L402 0	Powerline	246
L411 0	Fence Line	48
L413 0	Point-to-Point Line (Miscellaneous Linear)	4
L414 0	Property/Parcel Line (Including PLSS)	296
P000 1	Nonvisible Linear Legal/Statistical Boundary	11,393

P000 2	Perennial Shoreline	8,441
P000 4	Other non-visible bounding Edge (e.g., census water boundary, boundary of an areal feature)	2,584
R101 1	Railroad Feature (Main, Spur, or Yard)	2,269
R105 1	Carline, Streetcar Track, Monorail, Other Mass Transit Rail)	46
S110 0	Primary Road	1,409
S120 0	Secondary Road	8,543
S140 0	Local Neighborhood Road, Rural Road, City Street	89,971
S150 0	Vehicular Trail (4WD)	47
S163 0	Ramp	2,070
S164 0	Service Drive usually along a limited access highway	59
S171 0	Walkway/Pedestrian Trail	162

S174 0	Private Road for service vehicles (logging, oil, fields, ranches, etc.)	675
S175 0	Private Driveway	5

S178 0	Parking Lot Road	16
S182 0	Bike Path or Trail	1

**APPENDIX C. Characteristics of Clusters of Road Segments
Generated by a Cluster Analysis on Parcel Zoning Characteristics.**

Streets with one or more parcels were categorized by the land use of those parcels, based on a cluster analysis conducted with the *kmeans* command in R. The final analysis generated seven clusters based on the proportion of each of 17 land use types (see Appendix __). Also tested were a 9 cluster solution and an analysis based on size of properties. The selected solution was the most interpretable and also most informative regarding differences between street segments in crime and disorder.

The seven clusters, in the order they are referenced by the *Cluster* variable in the streets data set (values 1-7), and their main property types on the average street were as follows (note that proportions do not add up to 100% as this are only the land uses most commonly associated with such streets; other land uses may occasional appear on a given street in a cluster in small proportions):

1 = *Three-Family Residential with Assorted Other Uses* (3,136 streets with parcels, or 24%): 35% Three-Family Residential, 13% Residential Lot, 10% Apartment, 8% Two-Family Residential, 8% Single-Family Residential.

2 = *Mix of Two-Family and Single-Family Residential* (2,232 streets with parcels, or 17%): 56% Two-Family Residential, 18% Single-Family Residential.

3 = *Commercial* (1,298 streets with parcels, or 10%): 59% Commercial, 22% Commercial Lot.

4 = *Single-Family Residential Only* (3,239 streets with parcels, or 25%): 79% Single-Family Residential.

5 = *Exempt* (1,346 streets with parcels, 10%): 86% Exempt.

6 = *Condominiums* (1,244 streets with parcels, 10%): 56% Condominiums, 8% Single-Family Residential, 7% Two-Family Residential, 7% Three-Family Residential.

7 = *Mixed-Use Commercial* (553 streets with parcels, or 4%). 60% Residential-Commercial, 10% Commercial.

APPENDIX D. Unit Imputation

The City of Boston's Street and Address Management (SAM) system provides information about all properties in Boston, dividing properties into discrete units where possible. 75,394 properties (44%) in the assessment data set were separated into units. We tabulated the number of units for these, and then imputed the number of units for the remaining parcels using two methods.

For certain land uses, we assumed the number of units based on the definition of the land use itself. These included: residential 1-residential 3, which were set equal to the legal number of residential units associated with the designation (e.g., R2 = 2 units); commercial lots, residential lots, and condo parking, which were set equal to zero units as they have no buildings on them; condo main set equal to one unit as it is the lobby of a condo building. This accounted for 1,780 parcels that previously did not have unit data.

The remaining 73,614 properties (42%) were distributed across nine land uses: residential 4, apartments (residential with 7 or more units), commercial condominium, commercial, residential condominium unit, tax-exempt, tax-exempt (121A), industrial and mixed use (residential and commercial). We used regression-based imputation, leveraging data from assessments including the total assessed value for the property, land, and building (AV_TOTAL, AV_LAND, and AV_BLDG, respectively) and the total gross floor area and living area (GROSS_AREA and LIVING_AREA, respectively). Two of these variables themselves were not always complete, so we first imputed missing values for each based on the other variables. We did the modeling for the GROSS_AREA and LIVING_AREA variables (models `lm_md_gross_area` and `lm_md_living_area`) using generalized linear models. We then ran 9 separate generalized linear models, one for each of land use, that used assessed value and area to predict the number of units for all cases for which this information was known. The parameters from these models were then used to estimate the number of units (rounded to the nearest whole number) for those properties for which this information on the number of units was missing.
